(57) ABSTRACT

A process for the manufacturing of surface elements is provided herein. The surface elements can include a decorative upper layer and a supporting core. A supporting core with a desired format can be manufactured by press molding and provided with an upper side and a lower side. The upper side of the supporting core can be provided with a structure by a momentary pressing operation using a surface structured matrix. A ground coating can be provided on the structured upper side of the supporting core. A digitally printed decor comprising inks of at least four colors can be applied directly on top of the ground coating by an ink-jet type printer. The structure of the supporting core can enhance the realism of the decor, wherein the decor can be selected from the group consisting of woods and minerals.

TECHNICAL FIELD

The present invention relates to a process for the manufac- 25 turing of surface elements with a decorative upper surface of which the decorative elements have a considerably improved matching of the decor between adjacent surface elements.

BACKGROUND

Products clad with thermosetting laminate are common in many areas nowadays. They are mostly used where the demands on abrasion resistance are high, and furthermore where resistance to different chemicals and moisture is 35 desired. As examples of such products floors, floor skirtings, table tops, work tops and wall panels can be mentioned.

The thermosetting laminate most often consist of a number of base sheets with a decor sheet placed closest to the surface. The decor sheet can be provided with a pattern by desire. 40 Common patterns usually visualize different kinds of wood or mineral such as marble and granite.

One common pattern on floor elements is the rod pattern where two or more rows of rods of, for example wood, is simulated in the decor.

The traditional thermosetting laminate manufacturing includes a number of steps which will result in a random matching tolerance of up to ±5 mm, which is considered too great. The steps included in the manufacturing of a laminate floor is; printing decor on a paper of α-cellulose, impregnating the decorative paper with melamine-formaldehyde resin, drying the decorative paper, laminating the decorative paper under heat and pressure together with similarly treated supporting papers, applying the decorative laminate on a carrier and finally sawing and milling the carrier to the desired for- 55 mat. All these steps in the manufacturing will cause a change in format on the decor paper. It will therefore be practically impossible to achieve a desired match of patterns between the elements of a without causing great amounts of wasted laminate. The thermosetting laminate is a rather costly part of a 60 laminate floor.

SUMMARY

It has, through the present invention, been made possible to 65 overcome the above mentioned problems and a surface element with a decorative surface where the decorative pattern

2

between different surface elements is matching has been obtained. The invention relates to a process for the manufacturing of surface elements which comprises a decorative upper layer and a supporting core. The surface elements may be used as floor, wall or ceiling boards. The invention is characterized in that;

- i) A supporting core with a desired format is manufactured and provided with an upper side and a lower side.
- ii) The upper side of the supporting core is then provided with a décor, by for example printing. The décor is positioned after a predetermined fixing point on the supporting core.
- iii) The upper side of the supporting core is then provided with a protecting, at least partly translucent, wear layer by for example spray coating, roller coating, curtain coating and immersion coating or by being provided with one or more sheets of α -cellulose impregnated with thermosetting resin or lacquer.

The décor is suitably achieved by digitization of an actual media. The digitized décor is stored digitally in order to be used as a control function and original, together with possible control programs, when printing the décor.

The décor may accordingly be obtained by making a high resolution or selected resolution digital picture of the desired décor. This is suitably made by means of a digital camera or scanner. The most common décor will of course be different kinds of wood and minerals like marble, as these probably will continue to be preferred surface decoration in home and public environments. It is, however, possible to depict anything that is visible. The digitized version of the décor is then edited to fit the size of the supporting core. It is also possible to rearrange the décor in many different ways, like changing color tones, contrast, dividing the décor into smaller segments and adding other decorative elements. It is also possible to completely create the décor in a computer equipped for graphic design. It is possible to create a simulated décor so realistic that even a professional will have great problems in visually separating it from genuine material. This makes it possible to make for example floor boards with an almost perfect illusion of a rare kind of wood, like ebony or rose wood and still preserving trees under threat of extermination.

The digital décor is used together with guiding programs to control a printer. The printer may be of an electrostatic type or an ink-jet type printer. Most often the colors yellow, magenta, cyan and black will be sufficient for the printing process, but in some cases it might be advantageous to add white. Some colors are difficult to achieve using the colors yellow, magenta, cyan, black and white whereby the colors light magenta and light cyan may be added. It is also possible to add so called spot colors where specific color tones are difficult to achieve or where only certain parts of the color spectrum with intermixing shades is desired. The resolution needed is much depending on the décor that is to be simulated, but resolutions of 10-1500 dots per inch (dpi) is the practical range in which most décors will be printed. Under normal conditions a resolution of 300-800 dpi is sufficient when creating simulations of even very complex decorative patterns and still achieve a result that visually is very difficult to separate from the archetype without close and thorough inspection.

The digitally stored décor can also be used together with support programs when guiding other operations and procedures in the manufacturing process. Such steps in the operation may include procedures like identification marking, packaging, lacquering, surface embossing, storing and delivery logistics as well as assembly instructions.

It is advantageous to manufacture the supporting core in the desired end user format and to provide it with edges suited for joining before applying the décor and wear layer, since the amount of waste thereby is radically reduced. The décor matching tolerances will also be improved further by this 5 procedure.

The main part of the supporting core is suitably constituted by a particle board or a fiber board. It is, however, possible to manufacture the core that at least partly consist of a polymer such as for example polyurethane or a polyolefin such as 10 polyethylene, polypropylene or polybutene. A polymer based core can be achieved by being injection molded or press molded and can be given its shape by plastic molding and does therefore not require any abrasive treatment. A polymer based core may also contain a filler in the form of a particle or 15 fiber of organic or inorganic material, which besides the use a cost reducing material also will be used to modify the mechanical characteristics of the core. As an example of such suitable fillers can be mentioned; cellulose or wood particles, straw, starch, glass, lime, talcum, stone powder and sand. The 20 mechanical characteristics that may be changed is for example viscosity, thermal coefficient of expansion, elasticity, density, fire resistance, moisture absorption capacity, acoustic properties, thermal conductivity, flexural and shearing strength as well as softening temperature.

The upper surface, i.e. the surface that is to be provided with décor, is suitably surface treated before the printing. Such surface treatment will then incorporate at least one of the steps, ground coating and sanding. It is also possible to provide the surface with a structure that matches the décor 30 that is to be applied.

The translucent wear layer is suitably constituted by a UVor electron beam curing lacquer such as an acrylic, epoxy, or maleimide lacquer. The wear layer is suitably applied in several steps with intermediate curing where the last one is a 35 complete curing while the earlier ones are only partial. It will hereby be possible to achieve thick and plane layers. The wear layer suitably includes hard particles with an average particle size in the range 50 nm-150 µm Larger particles, in the range used to achieve abrasion resistance while the smaller particles, in the range 50 nm-30 µm preferably 50 nm-10 µm is used for achieving scratch resistance. The smaller particles are hereby used closest to the surface while the larger ones are distributed in the wear layer. The hard particles are suitably 45 constituted of silicon carbide, silicon oxide, α-aluminum oxide and the like. The abrasion resistance is hereby increased substantially. Particles in the range 30 mm-150 mm can for example be sprinkled on still wet lacquer so that they at, least partly, becomes embedded in finished wear layer. It is 50 therefore suitable to apply the wear layer in several steps with intermediate sprinkling stations where particles are added to the surface. The wear layer can hereafter be cured. It is also possible to mix smaller particles, normally particle sizes under 30 µm with a standard lacquer. Larger particles may be 55 added if a gelling agent or the like is present. A lacquer with smaller particles is suitably used as top layer coatings, closer to the upper surface. The scratch resistance can be improved by sprinkling very small particles in the range 50 nm-1000 nm on the uppermost layer of lacquer. Also these, so called nano- 60 particles, can be mixed with lacquer, which with is applied in a thin layer with a high particle content. These nano-particles may besides silicon carbide, silicon oxide and α -aluminum oxide also be constituted of diamond.

According to one embodiment of the invention, the trans- 65 lucent wear layer is constituted of one or more sheets of α-cellulose which are impregnated with melamine-formalde-

hyde resin. These sheets are joined with the core under heat and pressure whereby the resin cures. It is, also in this embodiment, possible to add hard particles with an average particle size in the range 50 nm-150 µm Larger particles, in the range 10 μm-150 preferably 30 μm-150 μm is foremost used to achieve abrasion resistance while the smaller of the particles, in the range 50 nm-30 µm preferably 50 nm-10 µm is used to achieve scratch resistance. The smaller particles is hereby used on, or very close to, the top surface while the larger particles may be distributed in the wear layer. Also here the particles advantageously are constituted of silicon carbide, silicon oxide, α -aluminum oxide, diamond or the like of which diamond, of cost reasons only is used as particles smaller than 1 μm . The sheets of α -cellulose are hereby suitably pressed together with the rest of the surface element in a continuous belt press with two steel belts. The pressure in the press is hereby suitably 5-100 Bar, preferably 20-80 Bar. The temperature is suitably in the range 140-200° C., preferably 160-180° C. It is also possible to utilize a discontinuous process where a number of surface elements can be pressed in a so called multiple-opening press at the same time. The pressure is then normally 20-150 Bar, preferably 70-120 Bar, while the temperature suitably is 120-180° C., preferably 140-160° C.

The décor on the surface elements is suitably constituted by a number of décor segments with intermediate borders, which borders, on at least two opposite edges coincides with intended, adjacent surface elements.

It is also desirable to provide the surface elements with a surface structure intended to increase the realism of the décor of the surface elements. This is suitably achieved by positioning at least one surface structured matrix, forming at least one surface structure segment on a corresponding décor segment or number of décor segments on the decorated surface of the surface element in connection to the application of wear layer. This matrix is pressed towards the wear layer whereby this will receive a surface with structure that enhances the realism of the décor.

When simulating more complex patterns, like wood block 10 μm-150 μm preferably in the range 30 μm-150 is foremost 40 chevron patterns or other décors with two or more divergent and oriented décors, it is suitable to use at least two structured matrixes which form one structure segment each. The structure segments are independent from each other in a structure point of view. The surface structure segments are intended to at least partly but preferably completely match the corresponding décor segments of the décor. The surface structure segments are accurately positioned on the décor side of the surface element in connection to the application of the wear layer, and are pressed onto this whereby the wear layer is provided with a surface structure where the orientation of the structure corresponds to the different directions in the décor.

> One or more matrixes preferably form the surface of one or more rollers. The surface element is then passed between the roller or rollers and counter stay rollers, with the décor side facing the structured rollers. The structured rollers are continuously or discontinuously pressed towards the décor surface of the surface element.

> Rollers containing two or more matrixes, are suitably provided with a circumference adapted to the repetition frequency of change of direction in the décor.

> It is also possible to apply the structure matrixes on the surface of a press belt. The surface element is then passed between the press belt and a press belt counter stay under continuous or discontinuous pressure between the structured press belt and the press belt counter stay.

> It is, according to one alternative procedure, possible to have one or more matrixes form the structure surface of one or

more static molds which momentary is pressed towards the decorative side of the surface element.

According to one embodiment of the invention, particularly characteristic décor segments such as borderlines between simulated slabs, bars, blocks or the like and also 5 knots, cracks, flaws and grain which is visually simulated in the décor, is stored as digital data. Said data is used for guiding automated engraving or pressing tools when providing said characteristic décor segments with a suitable surface structure, and that said engraving tool or pressing tool is 10 synchronized via the predetermined fixing point on the surface element.

The process described in the present application, for manufacturing surface elements is very advantageous from a logistic point of view since the number of steps when achieving a 15 new décor is radically reduced. It is, according to the present invention possible to use digitally created or stored data for directly printing the décor on a surface element by using an ink-jet printer or a photo-static printer. The so-called set up time will thereby be very short, whereby even very special 20 customer requirements may be met at a reasonable cost. It is according to the present invention possible to manufacture, for example, a world map in very large format, stretching over a great number of surface elements without any disrupting deviations in décor matching, to mainly the same cost as bulk 25 produced surface elements. Since the décor may be handled digitally all the way to the point of being applied to the surface of the core, set up times will be practically non-existent while at the same time a high degree of automation will be practicable. It is also possible to automatically provide the surface 30 elements with identification and orientation marking which would make the installation of complex décors, like world maps in the example above, much easier. This has so far been impossible.

The décor on the surface elements may be processed as 35 follows;

- A segmentation pattern is selected, the segmentation comprising at least two décor segments on each surface element. The shape, as seen from above, of the surface element is hereby selected from the group; triangular, 40 quadratic, rectangular, heptagonal, pentagonal and octagonal while the shape of the segments is selected from the group triangular, quadratic, rectangular, heptagonal, pentagonal, octagonal, circular, elliptical, perturbed and irregular.
- ii) A segment décor is then selected for each segment. The segment décor is selected from the group; digitized and simulated depiction of different kinds of wood, minerals and stone, different kinds of fabric, art work and fantasy based décor.
- iii) Each selection is made on a terminal where the selection emanates from a data base and that the selection is visualized via the terminal.

The décor is preferably achieved by digitization of an actual archetype or by partly or completely being created in a 55 digital media. The digitized décor is preferably stored digitally in order to be used as a control function and original, together with control programs and selection parameters, when printing the décor.

The dimensions of the surface to be covered by surface 60 elements are suitably entered into the terminal and support programs calculate an installation pattern. The installation pattern calculation is suitably also used for printing an assembly instruction. In order to visualize the selection the installation pattern calculation is possibly used for printing a miniaturized copy of the calculated installation with the selected pattern and décor. The dimensions of the surface to be cov-

6

ered by surface elements are suitably entered into the terminal and support programs further calculate décor and segmentation pattern matching between the surface elements.

The selections is preferably also used, together with support programs for controlling further steps in the manufacturing procedure selected from the group; identification marking, positioning marking, packaging, lacquering, surface embossing, storing and delivery logistics. An algorithm is suitably used for guiding the positioning of the décor segments and segmentation pattern so that a décor segment from one surface element may continue on an adjoining surface element. The control program is suitably used, together with décor data and selection parameters, for applying matching identification on the surface elements.

Surface elements manufactured as described above are suitably used as a floor covering material where the demands on stability and scratch and abrasion resistance are great. It is, according to the present invention, also possible to use the surface elements as wall and ceiling decorative material. It will however not be necessary to apply thick wear layer coatings in the latter cases as direct abrasion seldom occurs on such surfaces.

The invention is described further in connection to an enclosed figure, embodiment examples and schematic process descriptions showing different embodiments of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

A full and enabling disclosure of the present subject matter including the best mode thereof to one of ordinary skill in the art is set forth more particularly in the remainder of the specification, including reference to the accompanying figures, in which:

FIG. 1 is a top perspective view of a surface element according to the disclosure herein;

FIG. 2 is a flow diagram of a first process scheme; and FIG. 3 is a flow diagram of a second process scheme.

DETAILED DISCLOSURE

Accordingly, the figure shows parts of a surface element 1 which includes an upper decorative layer 2, edges 3 intended for joining, a lower side 4 and a supporting core 5. The process is initiated by manufacturing a supporting core 5 with a desired format and edges 3 intended for joining. The supporting core 5 is further provided with an upper side 1' suited for printing and a lower side 4. The upper side 1' of the supporting core 5 is then provided with a décor 2' by printing, utilizing an ink-jet printer. The décor 2' is oriented after a predetermined fixing point on the supporting core 5. The upper side 1' of the supporting core 5 is then provided with a protecting translucent wear layer 2" through curtain coating. The supporting core 5 is constituted by particle board or fiber board. The translucent wear layer 2" is constituted by a UVcuring acrylic lacquer which is applied in several steps with intermediate curing, of which the last one is a complete curing while the earlier ones are only partial curing. The wear layer 2" also includes hard particles of α -aluminum oxide with an average particle size in the range $0.5 \mu m-150 m$.

A surface structured matrix is positioned and pressed towards the décor side of the surface element 1 before the final curing of the acrylic lacquer whereby the surface of the wear layer 2" receives a surface structure 2" which enhances the realism of the décor 2'.

It is also possible to utilize two or more surface structured matrixes, each forming a structure segment, between which

the structure is independent, which will make it possible to simulate the surface structure of, for example, wood block chevron pattern décor.

A supporting polymer and filler based core is manufactured in the desired format and is provided with an upper side. a lower side and edges provided with joining members, such as tongue and groove. The upper side of the supporting core is then sanded smooth after which a primer is applied. A décor is then applied on the upper side by means of a digital photostatic five color printer. The colors are magenta, yellow, cyan, white and black. The décor is positioned from a predetermined fixing point in form of a corner of the supporting core, while the décor direction is aligned with the long side edge initiating from the same corner.

The basis for the décor is stored as digital data. This digital data has been achieved by digitizing a number of wood grain patterns with a digital camera. A number of rectangular blocks with a fixed width, but of varying length is selected and parted from the digital wood grain pictures. The width of the 20 rectangular blocks is selected so that three block widths equal the width of a supporting core. The digital images of the wood blocks are then classified after wood grain pattern and color so that a number of groups are achieved. The groups are; fair wood with even grain, dark wood with even grain, fair wood 25 with knots and flaws, dark wood with knots and flaws, fair cross-grained wood and finally dark cross-grained wood. Each group contains five different block simulations. An algorithm is feed into a computer which is used for the guiding of the printing operation so that the simulated wood blocks is digitally placed in three longitudinal rows and mixed so that two similar wood blocks never is placed next to each other. The algorithm will also guide the position of the latitudinal borderlines between the simulated wood blocks so 35 that they are unaligned with more than one block width between adjacent rows. It will also guide the latitudinal position of the borderlines so that it either aligns with the shorter edges of the supporting core or is unaligned with more than one block width. Another printer, also guided by the com- 40 element where, for example, chevron pattern, diamond patputer, is utilized for printing a running matching number on the lower side short side edges. The décor will hereby continue longitudinally over the surface elements and a perfect matching is obtained when the surface elements are placed in numerical order.

A basic layer of UV-curing acrylic lacquer is then applied by means of a roller. Particles with an average particle size in the range 150 µm is then sprinkled onto the still wet basic layer, whereby the main layer of UV-curing acrylic lacquer is applied by spray coating. The two layers of lacquer are then 50 partly cured using UV-light whereby the viscosity of the lacquer increases. A top layer of UV-curing acrylic lacquer with an additive in the form of hard particles with an average size of 2 µm, is then applied by means of a roller. Hard particles with an average size of 100 nm are then sprinkled on 55 top of the wet top layer, whereby the lacquer is partly cured with UV-light so that the viscosity increases. The still soft lacquer is then provided with a structure in the form of narrow, small, elongated recesses, simulating the pores of the wood. This will increase the realism of the décor. This is 60 achieved by alternating between two different structured rollers per row of simulated wood blocks. The structure of the rollers simulates even wood grain and cross-grained wood respectively. The rollers are alternately pressed towards the lacquered surface while it passes. The positioning of the 65 rollers is guided via the digitally stored data used for printing the décor as well as the fixing point used there.

It is according to one alternative embodiment possible to utilize one or more static molds with surface structure which momentary is pressed towards the décor side.

Especially characteristic décor segments such as borderlines between slabs, bars, blocks or the like and also knots, cracks, flaws and grain which is visually simulated in the décor, is suitably stored as digital data. This data is achieved by processing selected parts of the simulated wood blocks so that guiding data is achieved. Said data is then used for guiding an automated robot provided with an engraving tool or a press mold which provides the surface of the lacquer with a structure that matches said characteristic décor segments. The operation is also here synchronized via by the predetermined fixing point on the supporting core.

The lacquer is then completely cured with UV-light to desired strength, whereby the finished surface elements may be inspected by the naked eye or by a digital camera supported by a computer. The surface elements are then packed in batches and provided with identification markings.

The process above will make it possible to have a completely customer driven manufacturing where even very small quantities may be produced with the same efficiency as bulk manufacturing. Even though only one décor is described in connection to the process scheme above, it becomes clear to anyone skilled in the art, that a décor is changed very easily in the process. All of the important steps of the manufacturing such as printing, structuring, inspection, packaging and identification marking may be controlled and supervised by central processing data. This will make it logistically possible to manufacture customer designed décors. Such a process is exemplified as follows;

The customer utilizes a database via Internet or at a local dealer. It is also possible for another operator utilize a database. The database contains samples and/or reduced resolution copies of a great variety of standard decors which can be combined after predetermined parameters.

The parameters may, for example, concern a single surface tern and block pattern may be the choices of décor segmentation. It will here be possible to select a set of different simulations to randomly or by selected parameters fill the segments, for example, marble, birch and mahogany. The customer may also add an inlay from a design of his own which is digitized and processed, preferably automatically, to a desired format and resolution.

The parameters may alternatively include décor segments that require the space of several surface elements, for example a map over the world. The parameters may here further include fading of the larger design to a surrounding décor, surrounding frame of other décor etc.

The customer enters the measurements of the surface that is to be covered by the surface elements. The customer then makes selections from the database and is able to see his selection as a completed surface, either on screen or by printing. The visualization program used, is suitably also used for calculating installation pattern and presenting installation instructions with identification numbers on surface elements and where to cut the elements in order to make a perfect match. The surface elements may also be provided with removable matching lines on the decorative side making matching of décor between adjacent rows easier. The customer or dealer may then confirm his order via electronic mail where the pattern and décor is reduced to a code sequence and the order can be the direct input to the computer guiding the manufacturing process as described above. The customer

and/or dealer data follows the manufacturing process all the way to packaging and a fully customer guided manufacturing process is achieved.

A supporting fiber board based core is manufactured in the desired format and is provided with an upper side, a lower side and edges. The upper side of the supporting core is then sanded smooth after which a white primer is applied. A décor is then applied on the upper side by means of a digital ink-jet four color printer. The colors are magenta, yellow, cyan and black. The décor is positioned from a predetermined fixing point in form of a corner of the supporting core, while the décor direction is aligned with the long side edge initiating from the same corner.

The basis for the décor is stored as digital data. This digital data has been achieved by digitizing a number of wood grain patterns with a digital camera. A number of rectangular blocks with a fixed width, but of varying length are selected and parted from the digital wood grain pictures. The width of the rectangular blocks is selected so that three block widths 20 equal the width of a finished surface element. The digital images of the wood blocks are then joined digitally to form a rectangular surface of a specified size, for example, 200.times.1200 mm. A selected amount of such combinations of different blocks are designed as described above so that a 25 number of slightly different rectangular surfaces are achieved. The printer, or preferably a set of printers are positioned so that a desired number of rectangular décor surfaces with a specified intermediate distance is printed on the supporting core. The intermediate distance between the rectangular surfaces is the distance needed for parting and molding of edges. The décor printer or printers are also used for printing fixing points at predetermined positions. Another printer, also guided by the computer, is utilized for printing an identity code on the lower side of each intended finished surface 35

A basic layer of UV-curing acrylic lacquer is then applied by means of rollers. Particles with an average particle size in the range 75 µm is then sprinkled onto the still wet basic layer, whereby a top layer of UV-curing acrylic lacquer with an 40 additive in the form of hard particles with an average size of 2 μm is applied by means of a roller. Hard particles with an average size of 100 nm are then sprinkled on top of the wet top layer, whereby the lacquer is partly cured with UV-light so that the viscosity increases. The still soft lacquer is then 45 provided with a structure in the form of narrow, small, elongated recesses, simulating the pores of the wood. This will increase the realism of the décor. This is achieved by pressing rollers towards the lacquered surface while it passes. The positioning of the rollers are guided via the digitally stored 50 data used for printing the décor, as well as the fixing point used there when more complex and completely matching surface structures as described together with process scheme 1 is desired.

The lacquer is then completely cured with UV-light to 55 desired strength, whereby the finished surface element is cut into the predetermined formats which are provided with edges with joining functionality are molded by milling. The cutting and edge molding process is positioned from fixing point printed close to the décor. The surface elements may 60 then be inspected by the naked eye or by a digital camera supported by a computer. The surface elements are then packed in batches and provided with identification markings.

It is, according to an alternative procedure in the process, possible to cut and mold the edges at an earlier stage in the 65 process. It is suitable to apply and cure a protecting layer of lacquer on top of the printed décor followed by cutting and

10

molding of the edges. The remaining and main part of the wear layer is then applied as described in connection to process scheme 1 or 2 above.

The process above will make it possible to have a customer initiated manufacturing where even very small quantities may be produced with the same efficiency as bulk manufacturing. Even though only one décor is described in connection to the process scheme above, it becomes clear anyone skilled in the art, that décors is changed very easily in the process. All of the important steps of the manufacturing such as printing, structuring, inspection, packaging and identification marking may be controlled and supervised by central processing data.

The invention is also described through embodiment examples.

Example 1

A supporting core of medium density fiber board was sanded smooth. A layer of primer lacquer was applied on top of the fiber board. The primer was cured after which a décor was printed on top of the primer.

The build up of a wear layer was then initiated by applying 30 g/m² of UV-curing acrylic lacquer by means of roller coating. 20 g/m² of hard particles made of α -aluminum oxide with an average particle size of 70 µm were sprinkled on the still sticky lacquer. The lacquer was then exposed to a predetermined energy amount of UV-light so that it cured only partly and the viscosity was increased. Another 30 g/m² of UV-curing acrylic lacquer was then roller coated onto the already applied layer after which another 20 g/m² of α-aluminum oxide particles with an average particle size of 70 µm were sprinkled on the still sticky second coating. The lacquer was then exposed to a predetermined energy amount of UVlight so that it cured only partly and the viscosity was increased. Three layers of UV-curing acrylic lacquer were then applied by roller coating with intermediate partial curing as above. Each of the three layers had a surface weight of 20 g/m². The hard particles were completely embedded in the lacquer after the three layers were applied and a plane upper wear layer surface was achieved.

A top coating procedure was then initiated. A first layer of UV-curing acrylic topcoat lacquer was applied by means of a roller coater on top of the previous, partly cured, layers. The topcoat lacquer contained 10% by weight of hard particles of α -aluminum oxide with an average particle size of 10 μ m. The first layer was applied to a surface weight of 10 g/m². The topcoat lacquer was then exposed to a predetermined energy amount of UV-light so that it cured only partly and the viscosity was increased. A second layer of the topcoat lacquer was then applied and partly cured as described above. The wear layer was then provided with a surface structure by means of a surface structured roller. A third layer of the topcoat formulation was then applied on top of the structured wear layer. Also the third layer of top coat was applied to a surface weight of 10 g/m². The wear layer was then exposed to a predetermined energy amount of UV-light so that it cured completely.

The wear layer was then tested for abrasion resistance according to ISO 4586/2-88, where an IP value of 7100 turns was obtained. An IP value of 7100 turns is fully sufficient for floor covering materials with medium to heavy traffic like hotel lobbies, hallways and the like.

Example 2

A supporting core of medium density fiber board was sanded smooth. A layer of primer lacquer was applied on top

of the fiber board. The primer was cured after which a décor was printed on top of the primer. The build up of a wear layer was then initiated by applying 30 g/m² of UV-curing acrylic lacquer by means of roller coating. 20 g/m² of hard particles made of α -aluminum oxide with an average particle size of 70 $^{-5}$ um were sprinkled on the still sticky lacquer. The lacquer was then exposed to a predetermined energy amount of UV-light so that it cured only partly and the viscosity was increased. Another 30 g/m² of UV-curing acrylic lacquer was then roller coated onto the already applied layer after which another 20 g/m² of α -aluminum oxide particles with an average particle size of 70 µm were sprinkled on the still sticky second coating. The lacquer was then exposed to a predetermined energy amount of UV-light so that it cured only partly and the viscosity was increased. Three layers of UV-curing acrylic lacquer were then applied by roller coating with intermediate curing as above. Each of the three layers had a surface weight of 20 g/m². The hard particles were completely embedded in the lacquer after the three layers were applied and a plane 20 of 40 g/m². The hard particles were embedded in the lacquer upper wear layer surface was achieved. Also the uppermost of the three layers of lacquer was cured to a desired viscosity.

A second décor layer was then printed on top of the wear layer. The second décor layer, which was identical to the first décor closest to the core, was oriented and positioned so that 25 it completely matched the first décor.

The build up of an upper wear layer was then initiated by applying 30 g/m² of UV-curing acrylic lacquer by means of roller coating. 20 g/m² of hard particles made of α-aluminum oxide with an average particle size of 70 µm were sprinkled on 30 the still sticky lacquer. The lacquer was then exposed to a predetermined energy amount of UV-light so that it cured only partly and the viscosity was increased. Another 30 g/m² of UV-curing acrylic lacquer was then roller coated onto the already applied layer after which another 20 g/m² of α -alu- 35 minum oxide particles with an average particle size of 70 μm were sprinkled on the still sticky second coating. The lacquer was then exposed to a predetermined energy amount of UVlight so that it cured only partly and the viscosity was increased. Three layers of UV-curing acrylic lacquer were 40 then applied by roller coating with intermediate curing as above. Each of the three layers had a surface weight of 20 g/m². The hard particles were completely embedded in the lacquer after the three layers were applied and a plane upper wear layer surface was achieved.

A top coating procedure was then initiated. A first layer of UV-curing acrylic topcoat lacguer was applied by means of a roller coater on top of the previous, partly cured, layers. The topcoat lacquer contained 10% by weight of hard particles of α -aluminum oxide with an average particle size of 10 μ m. The 50 first layer was applied to a surface weight of 10 g/m². The topcoat lacquer was then exposed to a predetermined energy amount of UV-light so that it cured only partly and the viscosity was increased. A second layer of the topcoat lacquer was then applied and partly cured as described above. The 55 wear layer was then provided with a surface structure by means of a surface structured roller. A third layer of the topcoat formulation was then applied on top of the structured wear layer. Also the third layer of top coat was applied to a surface weight of 10 g/m². The wear layer was then exposed 60 to a predetermined energy amount of UV-light so that it cured completely.

The wear layer was then tested for abrasion resistance according to ISO 4586/2-88, where an IP value of 13500 turns was obtained. An IP value of 13500 turns is fully sufficient for 65 floor covering materials with heavier traffic like airports, railway stations and the like. The second layer of décor and

12

wear layer will add abrasion resistance without having obtained an unwanted hazy effect in the décor.

Example 3

A supporting core of medium density fiber board was sanded smooth. A layer of primer lacquer was applied on top of the fiber board. The primer was cured after which a décor was printed on top of the primer.

The build up of a wear layer was then initiated by applying 15 g/m² of UV-curing acrylic lacquer by means of roller coating. 20 g/m^2 of hard particles made of α -aluminum oxide with an average particle size of 70 µm were sprinkled on the still sticky lacquer. The lacquer was then exposed to a predetermined energy amount of UV-light so that it cured only partly and the viscosity was increased. One layer of UVcuring acrylic lacquer was then applied by roller coating and was partially cured as above. The layer had a surface weight after the layer of lacquer was applied and a mainly plane upper wear layer surface was achieved.

A top coating procedure was then initiated. A first layer of UV-curing acrylic topcoat lacquer was applied by means of a roller coater on top of the previous, partly cured, layers. The topcoat lacquer contained 10% by weight of hard particles of α -aluminum oxide with an average particle size of 10 μ m. The first layer was applied to a surface weight of 10 g/m². The topcoat lacquer was then exposed to a predetermined energy amount of UV-light so that it cured only partly and the viscosity was increased. The wear layer was then provided with a surface structure by means of a surface structured roller. A second, final layer of the topcoat formulation was then applied on top of the structured wear layer. Also the second layer of top coat was applied to a surface weight of 10 g/m². The wear layer was then exposed to a predetermined energy amount of UV-light so that it cured completely.

The wear layer was then tested for abrasion resistance according to ISO 4586/2-88, where an IP value of 3100 turns was obtained. An IP value of 3100 turns is fully sufficient for floor covering materials with light traffic like bedrooms, living rooms and the like.

The invention is not limited to the embodiments shown as these can be varied in different ways within the scope of the invention. It is for example possible to use so-called overlay sheets of α -cellulose impregnated with thermosetting resin instead of acrylic lacquer in the process described in connection to process scheme 1 and in particular in the process described in connection to process scheme 2. These sheets of α -cellulose which are impregnated with melamine-formaldehyde resin are joined with the supporting core through heat and pressure, whereby the resin cures. The wear resistance may also in this embodiment be improved by adding hard particles in the range 50 nm-150 µm to the wear layer.

What is claimed is:

1. A process for manufacturing surface elements comprising a decorative upper layer and a supporting core, the process comprising:

manufacturing a supporting core with a desired format by press molding, wherein the supporting core comprises an upper side and a lower side, wherein the upper side is provided with a structure by a momentary pressing operation using a surface structured matrix, wherein the surface structured matrix comprises a static mold;

providing a ground coating on the structured upper side of the supporting core; and

applying a digitally printed decor comprising inks of at least four colors directly on top of the ground coating by an ink-jet type printer;

- wherein the structure of the supporting core enhances the realism of the decor, wherein the decor is selected from 5 the group consisting of woods and minerals.
- 2. The process of claim 1, wherein the supporting core is manufactured using particles of inorganic material.
- 3. The process of claim 2, wherein the particles of inorganic material are selected from the group consisting of stone 10 powder, lime, talcum, glass and sand.
- 4. The process of claim 1, further comprises curing at least the ground coating.
- 5. The process of claim 1, wherein the ground coating is white
- **6**. The process of claim **1**, wherein the surface element is rectangular with two pairs of parallel opposite edges, wherein the printed decor is aligned with at least one edge.
- 7. The process of claim 1, wherein the printed decor has a resolution of 300 dots per inch (dpi) or more.
- **8**. The process of claim **1**, wherein the structure is directed in accordance with the alignment of the printed decor.
- 9. The process of claim 1, wherein the four colors comprise magenta, yellow and black.
- 10. The process of claim 1, wherein the four colors comprise white.
- 11. The process of claim 1, wherein the four colors comprise light magenta and light cyan.
